

Cpt S 450 Homework #7 Solutions

1.  $G$  is a DAG iff  $G$  does not have a loop. Hence, you only need to run SCC algorithm to make sure that there is no SCC containing more than one node. Complexity: linear –  $O(V + E)$ .

2. For this problem, the easiest way is to use automata theory approach (instead of DFS). From the decorated graph  $G$ , we construct a machine  $M$  as follows.  $M$  is equipped with an integer variable  $x$ . The nodes in  $G$  corresponds to the states in  $M$ . Hence a run of  $M$  corresponds a walk over  $G$ . Initially,  $M$  starts with state  $v$  and with  $x = 0$ .  $M$  walks on the graph while changing its state (for instance, if  $M$ 's current state is  $v_1$  and, then, when it walks on the edge  $(v_1, v_2)$ , the next state of  $M$  will be  $v_2$ ). In particular,  $M$  increments (resp. decrements)  $x$  by one when a red (resp. a green) edge is walked.  $M$  halts when the node  $v'$  is the current state and  $x \leq 0$ . Notice that  $M$  halts iff the answer to the question asked in the problem is false. Notice also that  $M$  can be modified into a PDA (use a stack to simulate the variable  $x$ ) and from 317, we know that we have an algorithm to check whether a PDA halts.

3. Notice that the answer to the question asked in the problem is false iff we have a path  $p$  from  $v$  to  $v'$  on which the number of red edges or the number of green edges is  $< 4$ . So, to solve the problem, you need only solve the following problems:

(1). Do we have a path from  $v$  to  $v'$  on which the number of red edges is 0, 1, 2, or 3?

(2). Do we have a path from  $v$  to  $v'$  on which the number of green edges is 0, 1, 2, or 3?

Both problems can be solved by a simply change to the DFS algorithm over  $G$ .

4. First notice that an infinite path must contain loops (since  $G$  has only finitely many states). The liveness property is not true iff there is an infinite path  $p$  from  $s_0$  such that every state on  $p$  is marked with not-good. The existence of such a  $p$  is equivalent to the following statement:

there is a finite path  $q$  on  $G$  such that  $q$  starts with  $s_0$  and  $q$  contains a loop and every state on  $q$  is marked with not-good.

Notice that the above statement can be justified the following algorithm:

Drop all states that are marked with good from graph  $G$   
Run SCC on  $G$   
For each state  $r$  in  $G$  do the following:  
    use DFS to check whether  $s_0$  can reach  $r$   
    check whether there is an edge from  $r$  to  $r$  in  $G$  or  $r$  is contained in a  
SCC that has at least two nodes  
    if both checkings are yes, then return yes;  
return no.
